Hypoglossal nerve stimulation (HNS) using the Inspire neurostimulation system (Inspire Medical Systems, Minneapolis, MN) is an emerging treatment modality for obstructive sleep apnea (OSA), involving synchronization of tongue protrusor stimulation and ventilatory effort during sleep. In a prospective multicenter trial, participants who met specific clinical and anatomical inclusion criteria had significant improvements in subjective and objective OSA outcome measures, and the treatment effect was maintained at long-term follow-up.1,2 There is no literature, however, on management of partial responders. This case report details the combination of HNS and oral appliance therapy (OAT) to successfully treat severe OSA after incomplete response with either treatment in isolation.

REPORT OF CASE

A 75-year-old male presented with a 12-year history of severe OSA. Sleep-related symptoms included loud disruptive snoring, witnessed apnea, nocturnal awakenings, and unrefreshing sleep. Although CPAP therapy provided years of subjective and objective improvement, he sought alternative treatment options due to multiple mask- and pressure-related side effects, persistent equipment-related nocturnal awakenings, and cumbersomeness with travel and camping. Oral appliance monotherapy with a custom mandibular repositioning device (TAP, Airway Labs, Carrollton, TX) was initiated two years prior to presentation, but inadequate symptom improvement and discomfort resulted in discontinuation (prior to repeat sleep testing). He later enrolled in the Inspire STAR Trial and underwent implantation of the HNS system after meeting the study inclusion criteria.1

Baseline STAR Trial diagnostic polysomnography (PSG) showed an AHI of 43.7, lowest arterial oxygen saturation (LSAT) of 75%, and arterial oxygen saturations below 90% (T90) for 33.8% of total sleep time. Six months after implantation, PSG with HNS therapy showed significant reduction in sleep apnea severity with an AHI of 11.6, LSAT 82%, and T90 of 10.2%. Patient-reported measures of daytime sleepiness and sleep-related quality of life were in the normal range at baseline and remained unchanged with HNS therapy. Per self-report and bedpartner report, snoring was significantly reduced with treatment from “loud/bedpartner leaves room” to “soft” on a visual analog scale but was not completely eliminated.

Over the subsequent year, attempts to further augment the effectiveness of HNS were made by the sleep physician/surgeon with positional therapy, topical nasal therapy, and adjustment of the electrical stimulation parameters. Although clinical, PSG, and satisfaction outcome measures remained significantly improved with nightly HNS use, mild OSA and bothersome snoring persisted.

The patient was then refitted with a new mandibular repositioning device to augment the HNS therapy. The Medley Gold (see Figure 1; TMD Technologies, Lilburn, GA) appliance was selected to allow increased anterior space for tongue protrusion that occurs with HNS therapy. Accommodation to the new appliance was successful with good subjective adherence; however, he developed intraoral discomfort, reporting that the stimulation now was too strong with combination therapy. OAT alone (HNS turned off) was tried for several weeks but again sleep-related symptoms, including loud snoring, recurred. The patient then underwent HNS reprogramming with the oral appliance in place to reduce stimulation amplitude (1.3V to 0.8V) and improve comfort.

Combination therapy with the new Medley Gold appliance and reduced HNS settings resulted in excellent subjective adherence and clinical improvement including resolution of snoring. A new PSG was completed with combination therapy.
Early in the study, HNS was wirelessly turned off to assess the effect of OAT alone (18.6 min) with clear return of sleep-disordered breathing and an AHI of 29.2 during this time. HNS therapy was then re-activated for the remainder of the night (286.9 min) during which combination therapy resulted in an AHI of 2.1 (Figure 1). The final PSG report for the entire night (305.5 min) confirmed complete objective control, with an overall AHI of 3.5, LSAT 86%, and T90 of 0.8%.

DISCUSSION

Interdisciplinary collaboration with multimodality treatment is an increasingly common approach particularly for severe OSA, although guidelines on patient phenotyping, sequencing of treatment, and specific algorithms are still lacking in the literature.3–5 In this first reported case of combination OAT and HNS therapy, symptoms and objective control of breathing were normalized as compared to partial OSA improvement with each in isolation. Furthermore, both the HNS stimulation amplitude and the degree of mandibular advancement could be reduced compared to when each was used as monotherapy.

Two key learning points may be noted in this case: (1) Stimulation parameters may be reduced on the HNS system with introduction of OAT, perhaps analogous to prior reports of reduced CPAP requirements with combination CPAP and OAT.4,5 (2) An oral appliance design with sufficient anterior room to accommodate tongue protrusion during active stimulation should be considered in HNS patients.
